## Supramolecular oligourethane gel as a highly selective fluorescent “on–off–on” sensor for ions†

Yulin Feng,<sup>‡a</sup> Nan Jiang,<sup>‡a</sup> Dongxia Zhu,<sup>id</sup> <sup>★a</sup> Zhongmin Su,<sup>id</sup> <sup>★a</sup> and Martin R. Bryce,<sup>id</sup> <sup>★b</sup>

Stimuli-responsive supramolecular gels (SMSGs) are an important class of smart materials. It is of practical importance to develop an SMSG which can both detect and remove toxic metal ions. We have designed and synthesized an aggregation induced emission (AIE)-active oligourethane (OU) gelator which self-assembles into a supramolecular gel (**OUG**), through hydrogen-bonding,  $\pi$ – $\pi$  stacking and van der Waals interactions. By taking advantage of the weak and dynamic nature of these non-covalent bonds, **OUG** shows stimuli-response to multiple factors. Importantly, **OUG** has the capacity for real-time detection and high selectivity for  $\text{Fe}^{3+}$ ,  $\text{HSO}_4^-$  and  $\text{F}^-$ . The lowest detection limits are in the range of  $5.89 \times 10^{-9}$  to  $8.17 \times 10^{-8}$  M, indicating high sensitivity. More importantly, **OUG** is shown to adsorb and separate  $\text{Fe}^{3+}$  from aqueous solution, with an absorbing rate of up to 97.5%. A simple writing board was fabricated, which could be written repeatedly and reused. **OUG** acts as a reversible and recyclable “on–off–on” fluorescence sensor via competitive cation– $\pi$  and cation–anion interactions. **OUG** has great potential as an environmentally sustainable probe for ions.

## Introduction

Stimuli-responsive supramolecular gels (SMSGs) have the ability to respond to a chemical substance,<sup>1</sup> light,<sup>2</sup> heat,<sup>3</sup> pH<sup>4</sup> or pressure.<sup>5</sup> They have been applied in chemical sensors,<sup>6</sup> displays,<sup>7</sup> drug deliveries<sup>8</sup> and other fields.<sup>9</sup> Responsive behavior can be achieved by a gel–sol state transition or by changing the luminescence.<sup>7,10</sup> The latter response works by changing the gel's fluorescence intensity or color, and can be free from the influence of temperature,<sup>2</sup> pH,<sup>11</sup> an oxidizing agent,<sup>8</sup> and other factors.<sup>12</sup> Therefore luminescence detection has considerably higher sensitivity and more reliable real-time response.<sup>13–15</sup> Traditional conjugated gelators usually suffer from aggregation-caused quenching (ACQ), which sharply weakens the emission behavior in aggregation or solid states, thereby limiting their applications.<sup>16</sup> The emergence of polymers/oligomers with aggregation-induced emission (AIE) properties has been a

breakthrough in the field.<sup>17,18</sup> In addition to their excellent emission characteristics, AIE-active supramolecular gels show strong absorption activity and synergistic effects because of their large contact area with analytes.<sup>19</sup>

Recently, our group has explored AIE-active poly/oligourethane-based unconventional luminophores, which are without typical polycyclic  $\pi$ -conjugated units. These materials show obvious advantages like environmental friendliness, excellent hydrophilicity, chain flexibility, ease of synthesis and structural versatility compared with traditional organic luminescent materials.<sup>20–22</sup>

$\text{Fe}^{3+}$  is an indispensable element in the process of oxygen uptake and metabolism.<sup>23</sup> However, an excess of  $\text{Fe}^{3+}$  might cause pathological diseases like cancer and organ dysfunction.<sup>24</sup>  $\text{F}^-$  and  $\text{HSO}_4^-$  also play essential roles in human biological processes,<sup>25,26</sup> although undue fluoride may cause kidney problems, dental and skeletal fluorosis.<sup>27</sup>  $\text{HSO}_4^-$  can produce poisonous  $\text{SO}_4^{2-}$  under acidic conditions, which will stimulate the skin and eyes and can even cause respiratory paralysis.<sup>28</sup> Thus, methods to efficiently detect these ions have received extensive attention. The established detection techniques, such as inductively coupled plasma spectroscopy,<sup>29</sup> high performance liquid chromatography (HPLC)<sup>30</sup> and electrochemical methods,<sup>31</sup> all require tedious sample preparations, sophisticated instruments and professional operators. However, fluorescent sensor molecules, which convert and amplify the signals into a visible

‡ These authors contributed equally to the preparation of this work.

and easily recognized fluorescent output, offer a more significant practical method.<sup>6,32</sup>

Herein, we report an AIE-active supramolecular oligourethane gel (**OUG**) and demonstrate its usage as a specific  $\text{Fe}^{3+}$  sensor in an aqueous environment. The material is based on the following design criteria: (i) inserting benzophenone into an oligourethane (OU) backbone provides  $\text{C}=\text{O}$  units with prominent hydrogen-bonding sites for self-assembly, and formation of oxygen clusters, which could enhance fluorescent emission.<sup>33</sup> (ii) Inserting linear 1,6-diisocyanatohexane offers strong van der Waals interactions among alkyl chains, limiting internal rotation of the molecular chains, thereby blocking the non-radiative pathways and favoring AIE. Taking advantage of the rich hydrogen bond acceptors/donors ( $\text{C}=\text{O}/\text{N}-\text{H}$ ) among the oligourethane skeleton,<sup>34–41</sup> we introduced solvents with hydrogen-bonding acceptor units ( $\text{C}=\text{O}$  or  $\text{S}=\text{O}$ ) as external crosslinking agents, to self-assemble a supramolecular oligourethane gel (**OUG**) relying on multiple hydrogen bonds.

## Results and discussion

### Synthesis and characterization

The OU was synthesized through a facile procedure as shown in Scheme S1 (ESI<sup>†</sup>), by the reaction of 4,4'-dihydroxybenzophenone, hexamethylene diisocyanate and DABCO in anhydrous tetrahydrofuran and end-capping with polyethylene glycol monomethyl ether to give a viscous solution. The product was purified by a counter precipitation method.  $^1\text{H}$  NMR and FTIR characterization data are given in Fig. 1a and in the ESI,<sup>†</sup> confirming the structure of OU. The  $M_n$  value of  $1814 \text{ g mol}^{-1}$ , calculated from the

$^1\text{H}$  NMR data, established that OU should be classified as an oligomer.<sup>42</sup> The FTIR spectra (Fig. S1, ESI<sup>†</sup>) showed absorbance bands at  $3323 \text{ cm}^{-1}$  and  $1706 \text{ cm}^{-1}$ , assigned to stretching vibrations of  $\text{N}-\text{H}$  and  $\text{C}=\text{O}$ , indicating the formation of amide bonds. Absorbance bands at  $2936 \text{ cm}^{-1}$  and  $2860 \text{ cm}^{-1}$  correspond to  $\nu(-\text{CH}_2-)$  and at  $1163 \text{ cm}^{-1}$  correspond to  $\nu(\text{C}-\text{O}-\text{C})$  stretching vibrations. The UV-Vis absorption spectrum of OU in the solid-state (Fig. S2, ESI<sup>†</sup>) showed a major peak at  $277 \text{ nm}$  from a  $\pi-\pi^*$  transition of the aromatic rings.<sup>43</sup>

### Self-assembly gelation

OU spontaneously self-assembles in certain solvents (notably dimethyl formamide and dimethylsulfoxide) transforming into a supramolecular gel (Table S1, ESI<sup>†</sup>). The lowest critical gelation concentration (CGC) of OU is 4% (w/v,  $10 \text{ mg mL}^{-1} = 1\%$ ), and the corresponding gel-sol transition temperature ( $T_{\text{gel}}$ ) is  $85-87^\circ\text{C}$ . In order to gain an insight into the self-assembly mechanism,  $^1\text{H}$  NMR, FTIR, XRD and urea addition experiments were conducted.  $^1\text{H}$  NMR spectra were recorded for different concentrations of OU in  $\text{DMSO}-d_6$  (Fig. 1b). The  $\text{H}_a$  and  $\text{H}_f$  proton signals are shifted *ca.* 0.04 and 0.03 ppm upfield compared to pure **OUG** upon adding  $25 \text{ mM Fe}^{3+}$ . Meanwhile, the signals of protons  $\text{H}_d$  (the NH groups) shifted slightly downfield *ca.* 0.01 ppm.<sup>44</sup> These results confirmed the H-bonding interactions between amide groups and van der Waals interactions between alkyl chains. Comparing the FTIR data before and after gelation (Fig. S1, ESI<sup>†</sup>), the  $\text{N}-\text{H}$  stretching absorbance bands of **OUG** are broader and move to significantly higher wavenumbers ( $3323$  to  $3361 \text{ cm}^{-1}$ ) in the solid state compared to the gel state: these data suggest hydrogen bonds play a critical role in the gelation process.<sup>45,46</sup>

It is well known that adding urea, which has a high propensity to form hydrogen bonds, can disrupt existing hydrogen bonds in a supramolecular structure.<sup>47,48</sup> Accordingly, adding urea (10 equiv.) into **OUG** and heating the gel, led to the formation of a sol. It was observed that after adding urea, the sol did not revert back to gel, even when the **OUG**-urea mixture was cooled at  $15^\circ\text{C}$  for several days, indicating that the gelation is driven by hydrogen bonds among OU molecular chains (Fig. 2a). Besides, the X-ray diffraction (XRD) peaks of **OUG**

**Fig. 1** (a)  $^1\text{H}$  NMR spectrum of OU in  $\text{DMSO}-d_6$  (\* indicates peaks from the solvent and water); H-atom labeling is shown on the structure of OU. (b) The partial  $^1\text{H}$  NMR spectra of OU in  $\text{DMSO}-d_6$  at different concentrations: (i) 0.925 mM, (ii) 3.7 mM, and (iii) 25.0 mM.

**Fig. 2** (a) Structure of OU and its self-assembly gelation process. (b) Schematic diagram for the ion sensing processes of **OUG**.

$2\theta = 20.54^\circ$ ,  $23.22^\circ$  corresponding to  $d$ -spacings of 4.32 Å and 3.83 Å, respectively, also indicated the presence of  $\pi$ - $\pi$  stacking interactions (Fig. S11b, ESI†), further promoting the self-assembly behavior. **OUG** showed weak fluorescence in the sol state, however, after transforming to the gel state, the emission intensity of **OUG** at 439 nm increased 6 times (Fig. S3, ESI†), indicating that **OU** is an AIE-active gelator.<sup>49</sup>

### Stimuli-responsive behaviors

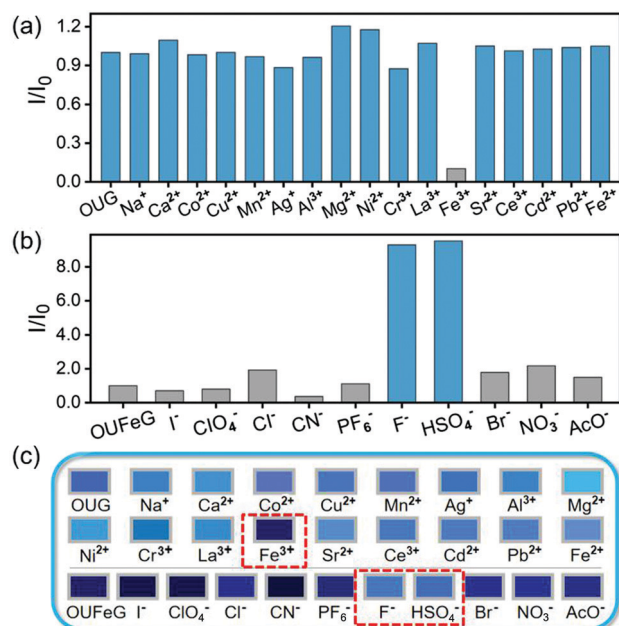

**OUG** exhibits a high selectivity to  $\text{Fe}^{3+}$  over other metal ions. By monitoring the change of fluorescence, we investigated the recognition characteristics of **OUG** towards metal ions. Using nitrate salts as the cation sources, an aqueous metal ion solution of  $\text{Na}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Cr}^{3+}$ ,  $\text{La}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Ce}^{3+}$ ,  $\text{Ag}^+$ ,  $\text{Al}^{3+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$  or  $\text{Fe}^{2+}$  ( $c = 0.2 \text{ M}$ ) was added to the **OUG** to generate the corresponding metal-gels.<sup>50–53</sup> As shown in Fig. 3a and c, initially, the **OUG** had a strong blue fluorescence emission. When different metal ions were added, only  $\text{Fe}^{3+}$  quenched the fluorescence of **OUG**. Thus, the **OUG** could effectively and selectively detect  $\text{Fe}^{3+}$ . To further evaluate the sensitivity of **OUG** for  $\text{Fe}^{3+}$ , the fluorescence behavior of **OUG** was monitored by continuous titrations with  $\text{Fe}^{3+}$ . As shown in Fig. S5a (ESI†), with the increasing addition of  $\text{Fe}^{3+}$  (0–1.1 equiv.), the emission intensity of the corresponding metal-gels (**OUG**) at 439 nm gradually decreased. The limit of detection (LOD) of **OUG** towards  $\text{Fe}^{3+}$  was calculated to be  $5.89 \times 10^{-9} \text{ M}$  based on the  $3\delta/S$  method<sup>54</sup> (Fig. S4 and S5a, ESI†), confirming the high selectivity of **OUG** as a sensor for  $\text{Fe}^{3+}$  compared with other reported sensor

systems (Table S2, ESI†). The high selectivity of **OUG** to  $\text{Fe}^{3+}$  is attributed to two reasons: firstly, unpaired electrons in  $\text{Fe}^{3+}$  cause a paramagnetic effect, prompting energy dissipation of excited states through non-radiative pathways.<sup>55</sup> Secondly, the high ionic strength of  $\text{Fe}^{3+}$  could easily induce the transfer of  $\pi$ -electrons from the urethane backbone to  $\text{Fe}^{3+}$  through cation- $\pi$  interactions.<sup>56</sup> both of these effects will cause the fluorescence quenching of **OUG**.

The response of **OUG** towards anions was further investigated, using tetrabutylammonium salts as the anion sources, adding aqueous solutions of anions including  $\text{HSO}_4^-$ ,  $\text{ClO}_4^-$ ,  $\text{I}^-$ ,  $\text{CN}^-$ ,  $\text{PF}_6^-$ ,  $\text{F}^-$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{NO}_3^-$ ,  $\text{AcO}^-$  ( $c = 0.2 \text{ M}$ ) to **OUG**.<sup>57–60</sup> As shown in Fig. 3b and c, when  $\text{HSO}_4^-$  and  $\text{F}^-$  were added the emission at 439 nm recovered immediately, whereas the other anions did not lead to a comparable fluorescence recovery of **OUG**. These phenomena confirmed the excellent selectivity of **OUG** towards  $\text{HSO}_4^-$  and  $\text{F}^-$ . This selectivity is explained by the strong coordinating capacity of  $\text{HSO}_4^-$  and  $\text{F}^-$  with  $\text{Fe}^{3+}$ , in contrast to (metal-free) **OUG**. These two anions could competitively bind to  $\text{Fe}^{3+}$  in **OUG** and induce the re-emission of **OUG**. Titration experiments evaluated the sensing efficiency of **OUG** to  $\text{HSO}_4^-$  and  $\text{F}^-$ . Limit of detection (LOD) values were calculated according to the  $3\delta/S$  method to be  $8.17 \times 10^{-8} \text{ M}$  for  $\text{F}^-$  and  $1.16 \times 10^{-8} \text{ M}$  for  $\text{HSO}_4^-$  (Fig. S5b and Fig. S7–S9, ESI†). Notably the LOD values of **OUG** are lower than many other reported  $\text{F}^-$  and  $\text{HSO}_4^-$  fluorescence sensors (Table S2, ESI†). The gel **OUG** selectively senses  $\text{Fe}^{3+}$ , and the metal-gel **OUG** selectively responds to  $\text{F}^-$  and  $\text{HSO}_4^-$ . This property makes gel **OUG** and metal-gel **OUG** act as an efficient “on-off-on” fluorescence sensor controlled by  $\text{Fe}^{3+}$ ,  $\text{HSO}_4^-$  or  $\text{F}^-$  with excellent reversibility. A simple regeneration treatment verified the recyclability of **OUG**. An anion solution ( $\text{F}^-$  or  $\text{HSO}_4^-$ ,  $2 \times 10^{-5} \text{ mol L}^{-1}$ ; 10 mL) was added into metal-gel **OUG**, stirring the mixture for 5 min, centrifuging and recycling **OUG** for again detecting ions. As shown in Fig. S10 (ESI†), after five consecutive cycles, the intensity of the **OUG** signal is essentially unchanged, indicating the excellent recyclability and reversibility of the **OUG** for the detection of  $\text{Fe}^{3+}$  and  $\text{HSO}_4^-$  or  $\text{F}^-$ .

### Mechanism of cation-anion sensor

When adding aqueous solution of  $\text{Fe}^{3+}$  into **OUG**,  $\text{Fe}^{3+}$  can diffuse in the solution. Due to the high ionic strength of  $\text{Fe}^{3+}$ , the  $\pi$ -electrons in the urethane groups of **OUG** are easily induced to form cation- $\pi$  interactions quenching the fluorescence. The recognition mechanisms of **OUG** to  $\text{Fe}^{3+}$  were investigated *via* a combination of  $^1\text{H}$  NMR, FTIR, XRD and SEM analysis. In the  $^1\text{H}$  NMR titration experiments, with the increasing amount of  $\text{Fe}^{3+}$  added into **OU**, protons  $\text{H}_d$ ,  $\text{H}_f$  and  $\text{H}_a$  all displayed clear upfield shifts (Fig. 4a), indicating that the **OUG** combined with  $\text{Fe}^{3+}$  *via* cation- $\pi$  interactions between the urethane groups and  $\text{Fe}^{3+}$ .<sup>56,61</sup> As Fig. 4b shows, by adding  $\text{F}^-$  or  $\text{HSO}_4^-$  (3.7 mM) into a sample of **OU** (with 2 equiv.  $\text{Fe}^{3+}$ ), all the protons recovered the chemical shifts as in the original **OU**:  $\text{H}_d$  (from 7.85 to 7.93 ppm and 7.09 to 7.19 ppm),  $\text{H}_f$  (from 3.94 to 4.03 ppm) and  $\text{H}_a$  (from 3.01 to 3.09 ppm and 2.87 to

**Fig. 3** (a) Fluorescence responses of **OUG** (in DMF, 10% (w/v)) toward  $\text{Fe}^{3+}$  and other metal ions at room temperature. (b) Fluorescence responses of **OUG** (in DMF, 10% (w/v)) toward  $\text{F}^-$ ,  $\text{HSO}_4^-$  and other anions at room temperature. All data represent the fluorescence intensity ratio  $I/I_0$  ( $I$  and  $I_0$  are the final fluorescence intensity and initial fluorescence intensity for the gel with each ion tested at 384 nm). (c) Photos of **OUG** fluorescence responses to various cations and anions.

Fig. 4 (a)  $^1\text{H}$  NMR titration spectra (298 K) of 0.925 mM OU with various equivalents of  $\text{Fe}^{3+}$  in  $\text{DMSO}-d_6$  solution. (b)  $^1\text{H}$  NMR spectra of (i) OU (ii) **OUFeG** (iii) **OUFeG** +  $\text{HSO}_4^-$  and (iv) **OUFeG** +  $\text{F}^-$ .

2.95 ppm), which indicated the cation–anion interactions between  $\text{Fe}^{3+}$  and  $\text{F}^-$  or  $\text{HSO}_4^-$  could release the  $\pi$ -electrons of urethane groups, thus recovering the fluorescence of **OUG**.

In the FTIR experiments (Fig. S11a, ESI $^\dagger$ ), when  $\text{Fe}^{3+}$  was added into **OUG** to form **OUFeG**, the stretching absorbance bands of N–H, C=O and C–O–C shifted from 3361  $\text{cm}^{-1}$ , 1708  $\text{cm}^{-1}$  and 1161  $\text{cm}^{-1}$  to 3480  $\text{cm}^{-1}$ , 1673  $\text{cm}^{-1}$  and 1158  $\text{cm}^{-1}$  respectively, which further confirmed that  $\text{Fe}^{3+}$  interacts with  $\pi$ -electrons of the urethane groups, thus influencing H-bonds between the amide groups.<sup>6,57</sup> After the addition of  $\text{F}^-$  or  $\text{HSO}_4^-$  into the **OUFeG**, the C=O, N–H and C–O–C all reverted to their initial positions (Fig. S11a, ESI $^\dagger$ ). These observations suggested that  $\text{F}^-$  and  $\text{HSO}_4^-$  competitively bound to  $\text{Fe}^{3+}$  rather than to **OUG**. Moreover, the XRD peaks of **OUG** moved with adding  $\text{Fe}^{3+}$  into **OUG**, and recovered when  $\text{F}^-$  or  $\text{HSO}_4^-$  was added into **OUFeG** (Fig. S11b, ESI $^\dagger$ ).

To get further insight into the mechanism of cation–anion sensing, as shown in Fig. 5, the SEM studies were carried out. Fig. 5a demonstrates that gel **OUG** shows a lamellar stacking structure with a smooth surface. This structure was converted into a honeycomb structure in the metal-gel **OUFeG** (Fig. 5b), while in gel **OUFeG** +  $\text{HSO}_4^-$  and **OUFeG** +  $\text{F}^-$ , the image again showed a smooth lamellar stacking structure (Fig. 5c and d). Such morphological change is attributed to the cation– $\pi$  interactions between **OUG** and  $\text{Fe}^{3+}$ , breaking hydrogen bonding

Fig. 5 SEM images of (a) **OUG**; (b) **OUFeG**; (c) **OUFeG** +  $\text{HSO}_4^-$ ; (d) **OUFeG** +  $\text{F}^-$ .

between the **OUG** chains and modifying the supramolecular structure.<sup>57,61</sup> After adding  $\text{F}^-$  or  $\text{HSO}_4^-$  into **OUFeG**,  $\pi$ -electrons of **OUG** were released, hydrogen bonds are rebuilt and the morphology is recovered. These experimental results indicated that the fluorescence of **OUG** can be reversibly switched by  $\text{Fe}^{3+}$  (off) and then by  $\text{F}^-$  or  $\text{HSO}_4^-$  (on), through repeated competition between cation– $\pi$  and cation–anion interactions (Fig. 2b).

### Application in the rapid removal of $\text{Fe}^{3+}$

The development of new sorbents for the sensing and extraction of metal ions from environmental and biological samples is of current importance.<sup>62,63</sup> The performance of **OUG** to effectively remove  $\text{Fe}^{3+}$  from aqueous solution was analyzed by atomic absorption spectrometry (Table S3, ESI $^\dagger$ ). Specifically, **OUG** (0.2 g) was added to a dilute aqueous solution of  $\text{Fe}^{3+}$  ( $1 \times 10^{-5} \text{ mol L}^{-1}$  in 10 mL water) and the mixture was stirred for 10 min. The precipitate was separated by centrifuging at 5000 rpm for 5 min and the supernatant was retained, the residual concentration of  $\text{Fe}^{3+}$  was about  $2.5 \times 10^{-7} \text{ mol L}^{-1}$ . Experimental results demonstrated that 97.5% of  $\text{Fe}^{3+}$  could be efficiently removed by **OUG** even from extremely dilute solutions, which indicated the excellent adsorption capacity of **OUG** towards  $\text{Fe}^{3+}$ .<sup>6,56,57,64</sup> As shown in Fig. S6 (ESI $^\dagger$ ), adsorption tests of **OUG** toward  $\text{Fe}^{3+}$  in the pH range from 4 to 10 showed that the adsorption of **OUG** toward  $\text{Fe}^{3+}$  showed excellent stability at different pH conditions (in the range of 92.1–97.5%). **OUG** can selectively detect with high-efficiency and rapidly remove toxic  $\text{Fe}^{3+}$ , offering potential practical applications in combating heavy metal ion pollution and in environmental remediation.

### Application as a writing display material

Based on the above-mentioned “on–off–on” properties, the **OUG** has a great potential as a rewritable fluorescent display material. As a proof-of-concept a rewritable board was constructed (Fig. 6). The detailed steps are described as follows: (i) **OUG** sol (10%) was poured onto a clean quartz plate surface and dried under ambient conditions to give a film emitting strong blue fluorescence under ultraviolet radiation (365 nm). (ii) Writing the symbol “Fe” on the film with a brush dipped in

Fig. 6 An erasable writing board of **OUG** based on its ion-controlled fluorescent switching properties.

aqueous  $\text{Fe}^{3+}$  solution (0.3 M), a dark “Fe” image was clearly displayed due to the fluorescence quenching effect of  $\text{Fe}^{3+}$  on OUG. (iii) The whole OUG film was transformed into a non-fluorescent display board by brushing with  $\text{Fe}^{3+}$  solution. (iv) Two new letters “S” and “F” could be written again with the same brushing method using  $\text{HSO}_4^-$  and  $\text{F}^-$  solutions (0.3 M), respectively. Visually, the letters emitted blue fluorescence under a UV lamp. Combining these practically very simple processes with the excellent recyclability of OUG (discussed above; Fig. S10, ESI<sup>†</sup>) means that OUG has promising applications as a fluorescent writing display material.

## Conclusion

In conclusion, a novel supramolecular AIE gel, OUG, was designed and synthesized by a straightforward “one-pot” procedure. The dynamic and reversible noncovalent interactions endow OUG with distinct advantages of a reversible and highly sensitive response to  $\text{Fe}^{3+}$ ,  $\text{HSO}_4^-$ , and  $\text{F}^-$ , acting as an “on-off-on” fluorescent sensor for these cationic and anionic species. Importantly, OUG can absorb up to 97.5%  $\text{Fe}^{3+}$  from a water environment. This rapid, simple, low cost and highly sensitive material has great potential for practical applications in intelligent sensing, handling heavy metal ion pollution and environmental remediation.
